Abstract: The COVID-19 pandemic introduced changes in people's lives that affected their mental health. Our study aimed to explore the level of psychological distress in the academic population during the lockdown period and investigate its association with the new working or studying conditions. The study sample included 9364 students and 2159 employees from five Italian universities from the study IO CONTO 2020. We applied linear regression models to investigate the association between home learning or remote working conditions and psychological distress, separately for students and employees. Psychological distress was assessed using the Hospital Anxiety and Depression Scale (HADS). In both students and employees, higher levels of distress were significantly associated with study/work–family conflicts, concerns about their future careers, and inadequacy of equipment; in employees, higher levels of distress were significantly associated with a lack of clarity on work objectives. Our results are in line with previous research on the impact of spaces and equipment in remote working/studying from home. Moreover, the study contributes to deepening the association between well-being and telework–family conflict, which in the literature is still equivocal. Practical implications require academic governance to promote sustainable environments both in remote and hybrid work conditions, by referring to a specific management by objectives approach.

Keywords: COVID-19; psychological distress; HADS; students; academic workers; teleworking; homeworking; e-learning

1. Introduction

The COVID-19 pandemic unexpectedly introduced drastic changes in people's private, social, and working lives, and confronted them with new health concerns. Prior to COVID-19, only two percent of employees in Italy regularly performed some form of telework, versus the European average of eight percent [1]. This scenario forced one to experiment with new ways of working and studying, with an unknown impact on well-being.

Previous research showed an increase of depressive and anxiety symptoms among the general population during the early stages of the COVID-19 pandemic [2,3]. In Italy, a survey indicated that a quarter of respondents had higher levels of anxiety and depression, and almost half had a sleep problem [4].

One of the first lockdown measures in Italy concerned the educational sector, and from 5 March 2020, all universities and schools were closed. Continuing teaching and research activities became an important challenge for the whole academic population. More specifically, some studies focused on the mental health of the academic community and evidenced that students and academic staff could be affected differently by the stressful events related to the COVID-19 breakdown [5]. For example, approximately one third of the academic population reported severe to moderate symptoms of psychological distress, with students showing higher levels than university workers [6,7]. Consistently, in our previous study, severe levels of anxiety or depression were reported by 20% of an academic sample and were associated with being a student [8]. Otherwise, university workers reported more concerns about health, social, and economic issues in comparison to students [7,9].

Hence, the next sections analyze more deeply the pandemic effect on students' and on university workers' well-being.

1.1. University Students' Well-Being during the Pandemic

Students were at a higher depression risk compared to the general population, even in the pre-pandemic period [10]. A recent review has shown a deterioration in students' mental health, noting a higher prevalence of depression, anxiety, and sleep disorders compared to prior to the pandemic [11,12].

Similar findings have been observed in Italian undergraduate students [13], where female students reported more anxiety symptoms than males [6,13–15].

The ongoing outbreak of COVID-19 has radically changed the nature and intensity of risk factors for students' well-being. First, online learning seems to have been a significant stressor for many students [16,17]. Students experienced changes in home learning that affected learning satisfaction and consequently psychological distress. Interruption of in-person activities, change of schedules, and transition of classes to virtual classrooms seem to have had a negative impact on students' quality of life, academic performance, and mental health. Most students reported a decrease in their academic performance [18] and lower satisfaction in the academic activity during the pandemic [19].

Second, changes in learning practice and schedules may have resulted in increased workload and extended work hours. An Italian study showed that many students complained about workload and fatigue due to online lectures, while reporting sufficient average satisfaction for the home learning approach [20]. By contrast, other studies reported a decrease in study hours [18] and students' difficulties in concentrating on their academic work [21].

Third, the home learning environment is another key factor when studying at home. A Slovenian study found that during the pandemic, students had experienced a worsening of study environment conditions, perceiving them as less suitable [22].

Moreover, students perceived a difficulty in combining studies with their family [23], and when compared to male students, female students reported greater interference in their academic work because of their domestic roles [9,20].

In addition, some studies analyzed the impact of the specific stressor of uncertainty on students' mental health. The threat of the pandemic has generated insecurity and concern for the future, affecting students' psychological distress [24–26]. More specifically, some studies revealed that students perceived a high degree of insecurity regarding the near future of the education process [27–29]. Others showed that students' psychological distress was related to the uncertainty of future career prospects [19], and increased concerns about the academic outcomes [15,27,28].

1.2. Academic Staff Well-Being during the Pandemic

In recent years, academics have experienced rapid changes that transversely affected all workers in university with health-impairment outcomes [30]. Additionally, the pandemic has brought radical changes for academic workers, but very little is known about how they were affected by new work conditions [31]. Even if pre-pandemic research has already shown that the academic population is at high risk of psychological distress, current studies suggest focusing more precisely on the impact of the adoption of compulsory teleworking during COVID-19 on well-being.

During the pandemic, workers were forced mandatorily and full-time to telework (the so call crisis-induced telework) [32]. These two conditions of telework have had a great impact on employee wellbeing [33].

Pre-pandemic studies emphasized both the advantages and difficulties of teleworking. Teleworking can facilitate flexibility in working spaces and times, greater autonomy, responsibility and work–life balance, reduced travel time, greater concentration on work and privacy [34,35]; but teleworkers have often faced some pitfalls, such as technostress, difficulties to maintain boundaries between work and nonwork, or professional isolation [36–38] and the evidence of the positive effect of telework on well-being and on performance-related outcomes was equivocal [39–41].

Evidence of the effect of telework on well-being remains still inconsistent: some studies described the negative effects of telework during the COVID-19 pandemic on mental health outcomes [42], whilst others involving non-academic workers found high teleworking satisfaction [43–45].

Moreover, several studies investigated the perception of advantages and disadvantages of teleworking in the pandemic, but more rarely, the effect of teleworking satisfaction on well-being, with few exceptions that demonstrated its impact [33,46]. Two Italian studies showed that teleworkers in the field of education and research appreciate teleworking less, and have higher levels of psychological distress, than in other working fields [46,47].

Another Italian study on university teachers showed how satisfaction with distance teaching is a protective factor for depression [48].

In the academic population, multiple teleworking risk factors could affect well-being: first, many perceived a higher workload (both increased workload pressure and longer working hours) [5,23,49,50]. A study during the pandemic on the general population found a larger prevalence of psychological distress in workers with a higher workload [51].

Literature also reported evidence of the negative effects of teleworking on family routines during the pandemic, such as the perception of a loss of boundaries between private and professional life and greater work–family conflict [5,49,52,53]. Several studies also showed an association between having young children and psychological distress [9,54], which seems stronger among females [31]. Teleworkers were more likely to report distress resulting from work–family conflict and being in confined spaces at home [45].

A study found that during the pandemic, academic staff perceived work environments as less suitable [22]. Workers with inadequate working spaces manifested higher levels of distress [46,51]. More specifically, inadequate work equipment resulted in being one major stressor for teleworkers during the pandemic.

Some studies analyzed the role of occupational concerns deriving from the economic crisis during the pandemic. The pandemic casts doubt on the financing of research projects and on the success of publication [53,55]. Workers reported more concerns about working conditions, such as losing jobs and income, than students [7], and job insecurity proved to be a significant predictor of anxiety and depression [52].

Moreover, research during COVID-19 showed that many managers struggled with the effective management of people working from home, and contemporary research, that many workers felt untrusted and micromanaged [56]. Focusing on leadership styles during teleworking in the pandemic, some studies pointed out that authoritarian leadership should be avoided [37] and that managers need to use skills of delegation and empowerment to provide their workers with greater autonomy over their work methods and timing, which in turn will promote worker health and performance [56]. Since increased autonomy and responsibility in their own work activity is a specificity required of teleworkers, a key element to support remote academic working quality is the reference to a “management by objectives” approach, according to which teleworkers’ goals have to be clearly set and leaders should trust, engage, and empower employees rather than incentivizing or controlling them [57–60]. Clear objectives can help workers in knowing what they need to do in their work, when constant communication is not possible.

1.3. Aim of the Study

Given the strong evidence of the impact of remote learning and working on academic community well-being, even in view of the above controversial data on research, further studies are needed to investigate the role of working and learning from home conditions on mental health. Indeed, since most of the reviewed studies conducted in the academic context investigated the levels of distress [7,9] but more rarely the impact of remote learning/working satisfaction, family–work/study conflict, and concern for the future, a deeper understanding of the impact of these context-specific variables on psychological distress seems important. Moreover, it seems important to consider simultaneously all the variables indicated above and to use a consistent sample size, rarely present in the reviewed studies.

In this direction, the aim of our study was to explore the level of psychological distress in a large sample of the Italian academic population during the lockdown period of the COVID-19 pandemic and to investigate its association with working and studying conditions. In relation to the literature, we tested whether the following factors associated with working and studying from home affect psychological distress: satisfaction with remote learning and working; work/study load; adequacy of the learning and working equipment; conflict with private life; and future uncertainty.

In addition, given the relationship nature of well-being, the study investigates the contribution of context-specific protective factors for mental health in the academic community during the pandemic period, i.e., the learning and work environment. More specifically, we explored the academic learning/work equipment and, only for workers, the clarity of work objectives, which has not yet been explored within the academic population during the COVID-19 pandemic.

In addition, since during the pandemic working women reported higher work–family conflict, as they were expected to devote more time to housework and childcare, we tested if there are gender differences in predictors of distress, by referring specifically to work–family conflict.

This study also expands previous work by exploring whether the contextual factors associated with psychological distress differ across students, faculty members, and administrative staff.

Based on the previous arguments and findings, we propose that psychological distress in the academic population is associated with the described contextual factors of working and studying from home during lockdown. Thus, we hypothesized:

Hypothesis 1a (H1a). *Home learning satisfaction will be significantly associated with lower student psychological distress.*

Hypothesis 1b (H1b). *Teleworking satisfaction will be significantly associated with lower worker psychological distress.*

Hypothesis 2a (H2a). *Increased learning load will be significantly associated with higher student psychological distress.*

Hypothesis 2b (H2b). *Increased workload will be significantly associated with higher worker psychological distress.*

Hypothesis 3a (H3a). *Adequacy of study equipment will be significantly associated with lower student psychological distress.*

Hypothesis 3b (H3b). *Adequacy of work equipment will be significantly associated with lower worker psychological distress.*

Hypothesis 4a (H4a). *Study–family conflict will be significantly associated with higher student psychological distress.*

Hypothesis 4b (H4b). *Work–family conflict will be significantly associated with higher worker psychological distress.*

Hypothesis 5a (H5a). *Concern for the future (studying uncertainty) will be significantly associated with higher student psychological distress.*

Hypothesis 5b (H5b). *Concern for the future (working uncertainty) will be significantly associated with higher worker psychological distress.*

Hypothesis 6 (H6). *Clarity of work objectives will be significantly associated with lower worker psychological distress.*

Hypothesis 7a (H7a). *The negative association between study–family conflict and student psychological distress will be stronger for women than for men.*

Hypothesis 7b (H7b). *The negative association between work–family conflict and worker psychological distress will be stronger for women than for men.*

2. Materials and Methods

Data were obtained from the project IO CONTO 2020, a study conducted on the academic population of five Italian universities during the first wave of the COVID-19 pandemic, which led to a nationwide lockdown starting from March 2020. Students and employees of the universities of Turin and Genoa (northern Italy), Pisa and Florence (central Italy), and Messina (southern Italy) were asked to complete a questionnaire about personal and familial characteristics, home features, studying and/or working conditions, lifestyle habits (e.g., physical activities, smoking and drinking behavior), health and psychological distress.

The project aimed to evaluate the impact of the restrictions on the psychophysical health of the academic population.

Each university collected data through the Moodle learning platform and dealt with anonymization and analyses at the local level. Aggregated data were then meta-analyzed by one single center.

IO CONTO 2020 was approved by the Bioethics Committee of the University of Pisa (Review No. 10/2020, 3 April 2020).

2.1. Study Population

About 220,000 students and 20,000 academic workers were invited to fill in the questionnaire: among them, about 18,000 individuals participated in the online survey (6% of

the students and 19% of the employees). For these analyses, working students (those who declared they had a current job, together with their studying activities) were excluded. As regards employees, only teaching–research staff and administrative and support staff who declared they had switched to remote working because of the COVID-19 restrictions were included in the sample.

2.2. Personal and Familial Information, Home Features

Some survey questions concerned socio-demographic characteristics. Participants were asked to give personal information, i.e., age and gender, family details, including household monthly income, presence of children, elderly or disabled members, and home features, such as the number of inhabitants and number of rooms. The presence of cohabitants working or studying from home or involved in in-person professional work with the public during the COVID-19 lockdown was recorded, together with changes in the economic situation and concern for the future due to economic uncertainty related to the pandemic.

2.3. Remote Working and Home Learning Features

The second section of the survey concerned working and studying features. Comparisons between past and current conditions were asked to participants in terms of workload and satisfaction of the new home-based situation. Five-score Likert scales (between 1, indicating strongly disagree, and 5, strongly agree) were used to measure overload, work (or study)–family conflicts, and concern for future career prospects. Participants were asked to evaluate their work (or study) place in terms of noise, needed technology, and comfort: the mean of the three answers resulted in a 4-score Likert scale able to measure the adequacy of work (or study) equipment (0, poorly equipped, and 3, fully equipped) [58]. Similarly, clarity of work objectives [58] for academic workers was measured by selecting four single items regarding clarity of expectations, clarity of duties and responsibilities, clarity of goals and objectives, and understanding of the role into the overall aim of the organization. The mean of the four answers resulted in a 4-score Likert scale (between 0, scarce clarity, and 3, optimal clarity).

2.4. Psychological Distress

Psychological distress was computed through the Italian version of the Hospital Anxiety and Depression Scale (HADS) [61–63], a self-assessment scale composed of 14 items, 7 related to anxiety and 7 to depression. The sum of each item, rated on a 4-score Likert scale from 0 to 3, returns a discrete value between 0 and 42 for the overall scale, and between 0 and 21 for the subscales.

2.5. Statistical Analysis

Frequencies and percentages were used to describe categorical variables, while means and standard deviations described continuous variables' distributions.

Linear regression models were fitted to investigate the association between psychological distress and home learning conditions for students or remote working for workers. Models were fitted including, at first, only personal and familial information, and home features, i.e., possible confounders (Model 1), and then confounders and home learning or remote working conditions, i.e., predictors, together (Model 2).

For each model, β coefficients and 95% Confidence Intervals (CI) were computed to estimate the association between predictors and psychological distress, i.e., to test the hypotheses from H1 to H7. Furthermore, the R-squared was computed to evaluate the proportion of variability of the outcome explained by confounders, then by confounders and predictors together.

The moderation effect of gender in the association between study (or work)–family conflicts and psychological distress were investigated through linear regression models

of the interaction between gender and study (or work)–family conflicts and adjusted by potential confounders, separately for students and workers (Model 3).

Linear regression analysis was performed separately in each university and the coefficients were combined through a random-effect meta-analysis. The R-squared from each center were combined weighting by the corresponding sample size.

All the analyses were performed in R (4.1.2 version) and Stata (SE17). All statistical tests were two-sided with a significance level of 0.05.

3. Results

Nearly half of both teaching–research staff and administrative or support staff were excluded because they had not switched from traditional to remote working after the beginning of lockdown, while approximately 30% of students were excluded because both students and workers (Figure 1). Overall, 11,523 participants (9364 students and 2159 employees) were considered for the analyses.

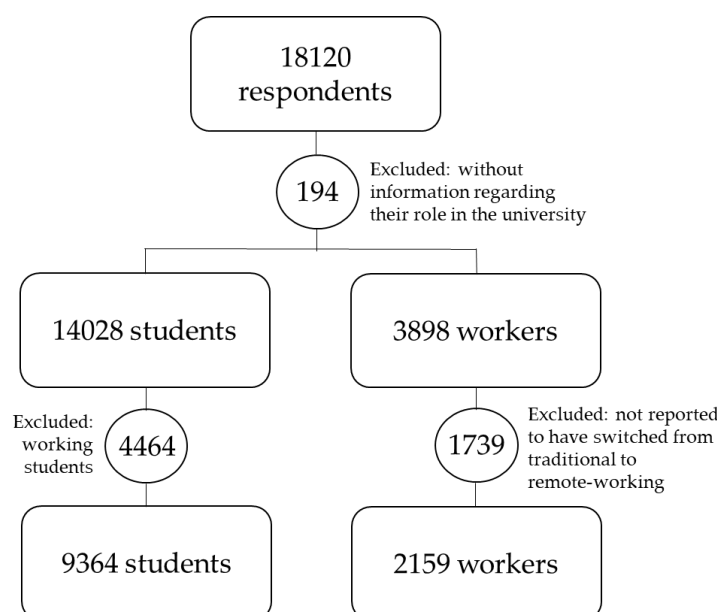

Figure 1. Workflow depicting exclusion criteria adopted for the study.

3.1. Descriptive Analyses—Students and Workers

Table 1 shows the characteristics of the 11,523 respondents considered for the analysis.

In the study sample, 9364 students were included; the mean age was almost 23 years and the majority of them (68.3%) were female.

About 30% of the students reported an increased workload from the beginning of the lockdown, and more than half of students considered home learning worse than traditional methods.

Noteworthy levels of concerns about the future of academic careers were expressed by students from the north to the south of Italy (mean value for the score: above 4 in a 1 to 5 rank).

According to HADS, overall, almost 30% of students were in a severe condition of psychological distress, with more than 22% and 13% presenting severe states of anxiety and depression, respectively, according to the HADS subscales.

Nearly half of academic workers belonged to the administrative staff (52.5%) and half were professors or researchers (47.5%). The majority of workers were female (62.8%) and had at least one child (62.1%).

Nearly half of academic workers expressed a negative judgement regarding teleworking compared to traditional habits, and more than 30% observed an increased workload during the lockdown.

Deep concern for future career prospects emerged from the mean value of its score (above 3 in a 1 to 5 rank), while on average, academic workers reported that their work-objectives were clearly defined and their work equipment was adequate (both above 2 in a 0 to 3 rank). Mean values for overload, work–family conflicts, and concern for household economic uncertainty were close to 2.5 in a 1 to 5 rank.

A severe condition of psychological distress was observed in 14.1% of academic workers according to HADS scores, and 6.5% and 10.1% of workers presented severe states of depression and anxiety, respectively, according to the subscales of HADS.

Table 1. Descriptive analyses of students and academic workers. Abbreviations: SD = Standard Deviation.

	Level	Overall N (%) Mean (SD)	Students N (%) Mean (SD)	Workers N (%) Mean (SD)

3.2. Linear Regression Models—Students

Table 4 shows estimated β -coefficients, 95% CI, and adjusted R-squared obtained through the linear regressions performed on the students' subsamples in every single center, then meta-analyzed.

In Model 1, the model built considering only the confounders (i.e., personal and familial information, and home features), 11% of the variance was explained.

Adding in Model 1 the studying-related variables increased the proportion of explained variance until 29%, as depicted in Table 4 in the second column (Model 2). An increase in overload during the COVID-19 lockdown was associated with higher HADS score values (H2a: $\beta = 0.57$, 95% CI = (0.33; 0.81)), while on the contrary, an increase in the score measuring adequacy of the equipment was associated with lower psychological distress (H3a: $\beta = -2.40$, 95% CI = (-3.35; -1.45)). The score measuring study–family conflicts was associated with a higher HADS score (H4a: $\beta = 1.14$, 95% CI = (0.93; 1.34)), as well as concern for the future (H5a: $\beta = 1.21$, 95% CI = (0.97; 1.46)). No significant association was found between home learning satisfaction and psychological distress (H1a).

Table 4. Linear regressions for students considering the total HADS as outcome. Confounders included for adjustment are: age, gender, household monthly income, elderly or disabled members, ratio between number of inhabitants and number of rooms, presence of cohabitants working or studying from home or involved in in-person professional work with the public, changes in the economic situation and concern for the future due to economic uncertainty related to the pandemic. Abbreviations: CI = Confidence Interval, * p value < 0.05.

The linear regression model built considering the interaction between gender and study–family conflicts (Model 3 in Table 4) did not show a significant moderation effect of gender in the association between study–family conflicts and the overall HADS score (H7a: $\beta = 0.31$, 95% CI = (−0.29; 0.90)).

3.3. Linear Regression Models—Academic Workers

Table 6 reports adjusted R-squared, estimates and 95% CI obtained through the linear regressions performed on the academic workers subsamples and then meta-analyzed.

In Model 1, the model built considering only the confounders (i.e., personal and familial information, and home features), 10% of variance was explained.

Similar to what was observed for students, adding in Model 1 the working-related variables increased the proportion of explained variance up to 26%. An increase in the score measuring adequacy of the equipment was associated with lower psychological distress (H3b: $\beta = -1.25$ *, 95% CI = (−2.07; −0.42)), as well as an increase in the clarity of working objectives (H6: $\beta = -1.00$, 95% CI = (−1.65; −0.34)). The score measuring working–family conflicts was associated with higher HADS score (H4b: $\beta = 0.64$, 95% CI = (0.17; 1.11)), as well as concern for the future (H5b: $\beta = 1.28$, 95% CI = (0.67; 1.89)). No significant association was found between remote working satisfaction (H1b) or overload (H2b) and psychological distress.

Table 6. Linear regressions for employees (professors, researchers, and administrative staff) considering the total HADS as outcome. Confounders included for adjustment are: age, gender, household monthly income, elderly or disabled members, children, ratio between number of inhabitants and number of rooms, presence of cohabitants working or studying from home or involved in in-person professional work with the public, changes in the economic situation, concern for the future due to economic uncertainty related to the pandemic, and role (professors and researchers or administrative staff). Abbreviations: CI = Confidence Interval, * p value < 0.05.

The linear regression model built considering the interaction between gender and study–family conflicts (Model 3 in Table 6) did not show a significant moderation effect of gender in the association between work–family conflicts and psychological distress (H7b: $\beta = 0.08$, 95% CI = $(-0.38; 0.54)$).

4. Discussion

Previous studies showed the negative effects of forced lockdown (meaning restrictions on mobility, movement, and relationships) during the COVID-19 pandemic on mental health: isolation and lockdown have increased levels of depression and anxiety in both the whole population [64] and among students [19,65–67].

Our study aimed at investigating psychological distress and its association with working and studying conditions across students, faculty members, and administrative staff from a large Italian academic sample.

In our survey, almost 30% of students evidenced a severe condition of psychological distress. The proportion of students reporting severe levels of anxiety or depression amounted for 22% and 13%, respectively. These proportions are similar to the proportions observed in other European studies on university communities. For example, the percentage of students experiencing high levels of anxiety was 27% and 21% in French [68] and Spanish [7] university samples, respectively. Monteduro [69] observed that nearly 32% of students experienced loneliness, sadness, isolation, and depression. Undergraduate students present higher levels of distress than the general population [19] and university workers [7]. The worsening of social relationships due to isolation and loneliness seems to be particularly relevant to explaining the negative impact of lockdown on young adults' mental health [70].

Students at the University of Messina had the highest levels of anxiety compared to their peers from the other universities (Supplementary Materials). This result is in line with findings from earlier Italian research comparing three Italian universities located in the South, Centre, and North of Italy (University of Messina, Marche Polytechnic in Ancona, and University of Udine, respectively) [66]. The different levels of psychological distress observed at a territorial level may be linked to the marked spatial heterogeneity of the epidemic spread in Italy [71] and to the regional differences in the Italian socio-economic structure, confirming that the psychological consequences of the pandemic crisis are unequally distributed [72,73].

As expected, the regression models showed that, among students, the levels of HADS scores were exacerbated by the conflicts due to combining and managing family–study roles, the study overloads due to the changes in learning conditions after the beginning of the lockdown, and the future uncertainty about studying. Only an adequate study equipment was able to reduce it, while the home learning satisfaction did not show a significant effect in the multivariable model. Our results confirmed our Hypotheses 4a, 2a, 5a, 3a, and disputed Hypothesis 1a. Our results confirmed previous studies which showed that the transition to virtual classrooms had a negative impact on students' mental health, by increasing workload and family–study conflicts. In addition, uncertainty about the future affected the level of psychological distress. In this regard, it is important to consider that expectations and future uncertainty are risk factors and increase distress levels [74]. Moreover, our results showed the importance of the learning environment as a resource to reduce psychological distress. In particular, the academic learning equipment can be considered a protective factor for students' mental health.

Furthermore, we found that demographic (gender and age), social (living with the disabled, elderly and workers at risk of contagion) and economic (economic uncertainty, income) variables were associated with psychological distress: female students reported higher levels of total HADS, as well as young students compared to older ones [75,76]. In fact, the reduced ability of the youth to tolerate uncertainty about the future could explain

these differences in terms of mental health reactions [77]. Our findings, in line with previous analyses, where university students showed high rates of anxiety/depression and financial instability due to the pandemic all over the world [78–80], became more problematic considering the Italian context. Indeed, our Italian labor market still heavily penalizes women and young people who are often trapped in insecure, bad jobs and have a higher degree of precariousness.

As suggested by Brunori et al. [81], youth and women will be one of the most affected groups by the impact of the COVID-19 crisis on the labor market, because they are more exposed to the prospect of unemployment and economic risks. Moreover, Fetzner et al. [82] underlined that young adults and women are two categories at high risk of economic anxiety. This evidence is also confirmed in our research.

An unexpected result is that the students with a high household monthly income have the highest level of psychological distress. This can be partially explained by the different lifestyles between low- and high-income households. Students with a high income generally spend more time on leisure, social, and cultural activities and therefore, may have been more affected by the lack of these activities during the lockdown.

Other factors affecting psychological distress are related to social aspects or care work into the family: it is greater in students who live with elderly or disabled people or with family members or other people involved in activities where there is close contact with people and therefore, a potentially greater risk of contagion.

Finally, even though in our study both the variables, study–family conflict and gender were significantly associated with psychological distress, their interaction was not (Hypothesis 7a), suggesting that both males and females struggled with balancing studying and familial conditions, equally.

In relation to the results involving the academic staff, the lockdown measures imposed a new organization of work for professors, researchers, and administrative staff transforming their work in working remotely.

According to the literature [64], greater levels of anxiety, depression, and stress commonly affect people with higher levels of education, making academic staff a particularly relevant sample to evaluate the impact of the current pandemic on psychological distress.

In our study, 14.1% of academic workers reported severe conditions of psychological distress, and 6.5% and 10.1% showed, respectively, severe states of depression and anxiety.

For the academic workers, the variables associated with the increase in the level of stress mainly concern the work and organizational sphere and work–family balance. In fact, clarity of work objectives and equipment adequacy decreased the level of general psychological distress, confirming Hypotheses 6 and 3b. This seems to suggest the level of distress was not directly associated with the general satisfaction for remote work or overload (indeed H1b and H2b were disputed), but more precisely, with the two organizational key elements, which are specifically related to remote working: the adequacy of work equipment and the clarity of work objectives, that are significant also in the multi-variable model.

In relation to the first element, the results show the importance of the managerial approach specifically used for remote working. Having experienced high levels of clarity of work objectives was a protective factor for employees' mental health, considering the difficulties and uncertainties of the rapid transition to new ways of working. In relation to the second element, our study is in line with previous research that has highlighted the impact of adequate working spaces and equipment on teleworking from home during the pandemic [43,46]. These findings contribute to understanding the importance of the management model used for teleworking in the academic context and underline the centrality of university governance in managing remote work and promoting appropriate policies.

Besides, we found that the level of general psychological distress increases for individuals that have experienced work–family conflicts during the pandemic, as well as for

those subjects worried about the economic uncertainty and their working future, confirming the Hypotheses 4b and 5b. These results are in line with the literature. The limitation of time dedicated to work because of family constraints during the pandemic can be derived from an increase in the domestic activities connected, for example, to the impossibility of receiving paid help.

Furthermore, we observed higher levels of psychological distress in women compared to men. For Carreri and Dordoni [83], compared to men, academic women had to struggle more during the pandemic due to the greater burden in housework, family care, and emotional support. As suggested by Minello et al. [84], gender disparities were present in the academy, even before the lockdown, but the pandemic may have aggravated the sense of insecurity and their fear for the future of their careers.

Even though we hypothesized a potential interaction between work–family conflict and gender, our analyses did not support it, disputing Hypothesis 7b. This could be related to the fact that during the lockdown men also experienced an increased level of family–work conflict compared to the past, which tends to level out gender differences. Due to the forced confinement for the COVID-19 pandemic, maintaining boundaries between work and nonwork has been perceived as difficult especially for workers with school-age children during the closure of educational activities and because of the impossibility of receiving paid help. A further research development could be to consider not only the moderation effect of gender on the family–work conflict, but the status of “parenthood” and the presence of pre-school or school-age children (for a literature review, see Shirmohammadi et al. [85]).

5. Limitations and Conclusions

Our study presents some limitations.

At first, the research design is cross-sectional, which reduces the internal validity of conclusions. As such, further investigation of the study should involve a longitudinal analysis to test how the relations investigated vary over time.

Then, psychological distress was measured through a self-reported questionnaire within an online survey, whereas an expert-administered clinical interview protocol could have contained the risks of bias related to self-administration.

In addition, there was a high non-response rate and the volunteer participation to the study may have led to a sample selection problem: it is therefore not possible to generalize the results to the universe (the Italian university population).

Despite these limitations, we can acknowledge the following strengths.

Firstly, our results demonstrated the importance of contextual and organizational variables to protect academic well-being. For both students and academic workers, uncertainty about the future (both economic and working/studying) increased psychological distress, while the adequacy of study/work equipment decreased it.

Secondly, our results confirmed that the management by objectives approach could reduce academic workers’ psychological distress.

Our exploratory analysis of factors associated with psychological distress in the academic population could be enriched with further in depth-analysis: e.g., distinguishing the role of risk and protective factors between professors–researchers and administrative staff or investigating the role played by parenthood and by the presence of children of school and pre-school age in work/learning–family conflict under remote working/learning conditions.

Thirdly, the practical implications of the study: the importance of realizing and implementing strategies for prevention, assessment, and intervention, of psychological distress in academic contexts, with specific attention to remote work and study. The study highlighted the need for taking into account the responsibility of academic governance in promoting sustainable environments both for academic workers and students, even in remote or hybrid work and learning. Monitoring and preventing the vulnerability of the

academic population seems to require specific devices, such as university counselling services, and most of all, a managerial approach sensitive to workers' quality of life, even by including specific target needs and managing by diversity approach. In fact, during the lockdown, universities often arranged remote work and online teaching, with a scarcity of alternative managerial models, guidelines, and policies, in the way best definable as working-from-home. The flexibility of location and working time that telework is supposed to offer was no longer allowed, nor in many cases were the technological infrastructures, as well as an adequate working environment, provided.
