Abstract

A growing number of emerging SARS-CoV-2 variants is being identified worldwide, potentially impacting the effectiveness of current vaccines. We report the data obtained in several Italian regions involved in the SARS-CoV-2 variant monitoring from the beginning of the epidemic and spanning the period from October 2020 to March 2021.

Keywords: SARS-CoV-2 virus, Complete genome sequencing, COVID-19 RT-PCR testing, Spike protein, Viral variants

Background

Starting from April 2020 when the Cluster 5 [1] variant was first described, multiple SARS-CoV-2 (Severe acute respiratory syndrome coronavirus 2) variants have emerged in different parts of the world. The Alpha variant (formerly known as B.1.1.7) was first identified in the UK from a sample obtained in late September 2020 [2, 3] (<https://www.who.int/en/activities/tracking-SARS-CoV-2-variants/#:~:text=Naming%20SARS%2DCoV%2D2%20variants,scientists%20and%20in%20scientific%20research>), Beta variant (B.1.351) was identified in October 2020 in South Africa [4], and Gamma variant (P.1) was identified in Brazil in December 2020 [5]. These variant strains show multiple changes (deletions and substitutions) in the spike protein (9 in B.1.1.7, 10 in B.1.351, and 12 in P.1) compared with the reference genome Wuhan-Hu-1 sequence (EPI_ISL_406800), some of which affect the receptor-binding domain (RBD) region. The major

issue with these variants is their potential to outcompete and rapidly replace formerly prevalent lineages, first in the areas where they likely emerged and subsequently spread in many other countries [6–8]. Increased SARS-CoV-2 diversity raises the concern of escape from pre-existing immunity, elicited either by previous infection or by vaccination.

Main text

Here, we report data from several Italian centers located in Campania, Lazio, Lombardy, Liguria, Marche, Piedmont, Tuscany, Sicily and Umbria, involved in the SARS-CoV-2 variant monitoring from the beginning of the epidemic and spanning the period from October 2020 to March 2021.

Globally, we analysed data from 3744 samples obtained by different techniques: RT-PCR variant screening assays (n=2095), spike Sanger or Next Generation Sequencing (n=649) and Whole Genome Sequencing (WGS; n=1000) (Table 1). Data for the analyses were obtained from each center as a part of routine test of variant monitoring or for research purpose for those not involved in national surveillance but included in the SCIRE (SARS-CoV-2 Italian Research Enterprise) collaborative group.

Table 1 Summary of analyzed data

Month	WGS (n = 1000)	Spike (n = 649)	Real time (n = 2095)	Total (n = 3744)
October 2020	137	20	1	158
November 2020	168	31	0	199
December 2020	139	34	0	173
January 2021	291	86	388	765
February 2021	193	214	827	1234
March 2021	72	264	879	1215

WGS whole genome sequencing

SARS-CoV-2 RNA positive swabs were collected from the respiratory tract of individuals who were either hospitalized or tested within screening programs. SARS-CoV-2 RNA was extracted using different commercial kits such as the Kit QIAasymphony DSP Virus/Pathogen Midi kit on the QIAasymphony automated platform (QIAGEN, Hilden, Germany), the NucleoMag 96 Virus (Macherey-Nagel, Dueren, Germany) on automated KingFisher™ ml Magnetic Particle Processors (Thermo Fisher Scientific, Waltham, MA, USA) and manually with QIAamp Viral RNA Mini Kit (QIAGEN, Hilden, Germany). RT-PCR variant screening assays were performed using TaqPath COVID-19 test (Thermo Fisher Scientific, USA), COVID-19 variant Catcher kit (Clonit srl, Milan, Italy), Allplex SARS-CoV-2 Variants (Arrow Diagnostics srl, Genoa, Italy) or multiplexed RT-qPCR developed by English consortium (https://www.protocols.io/view/multiplexed-rt-qpcr-to-screen-for-sars-cov-2-b-1-1-br9vm966?version_warning=no).

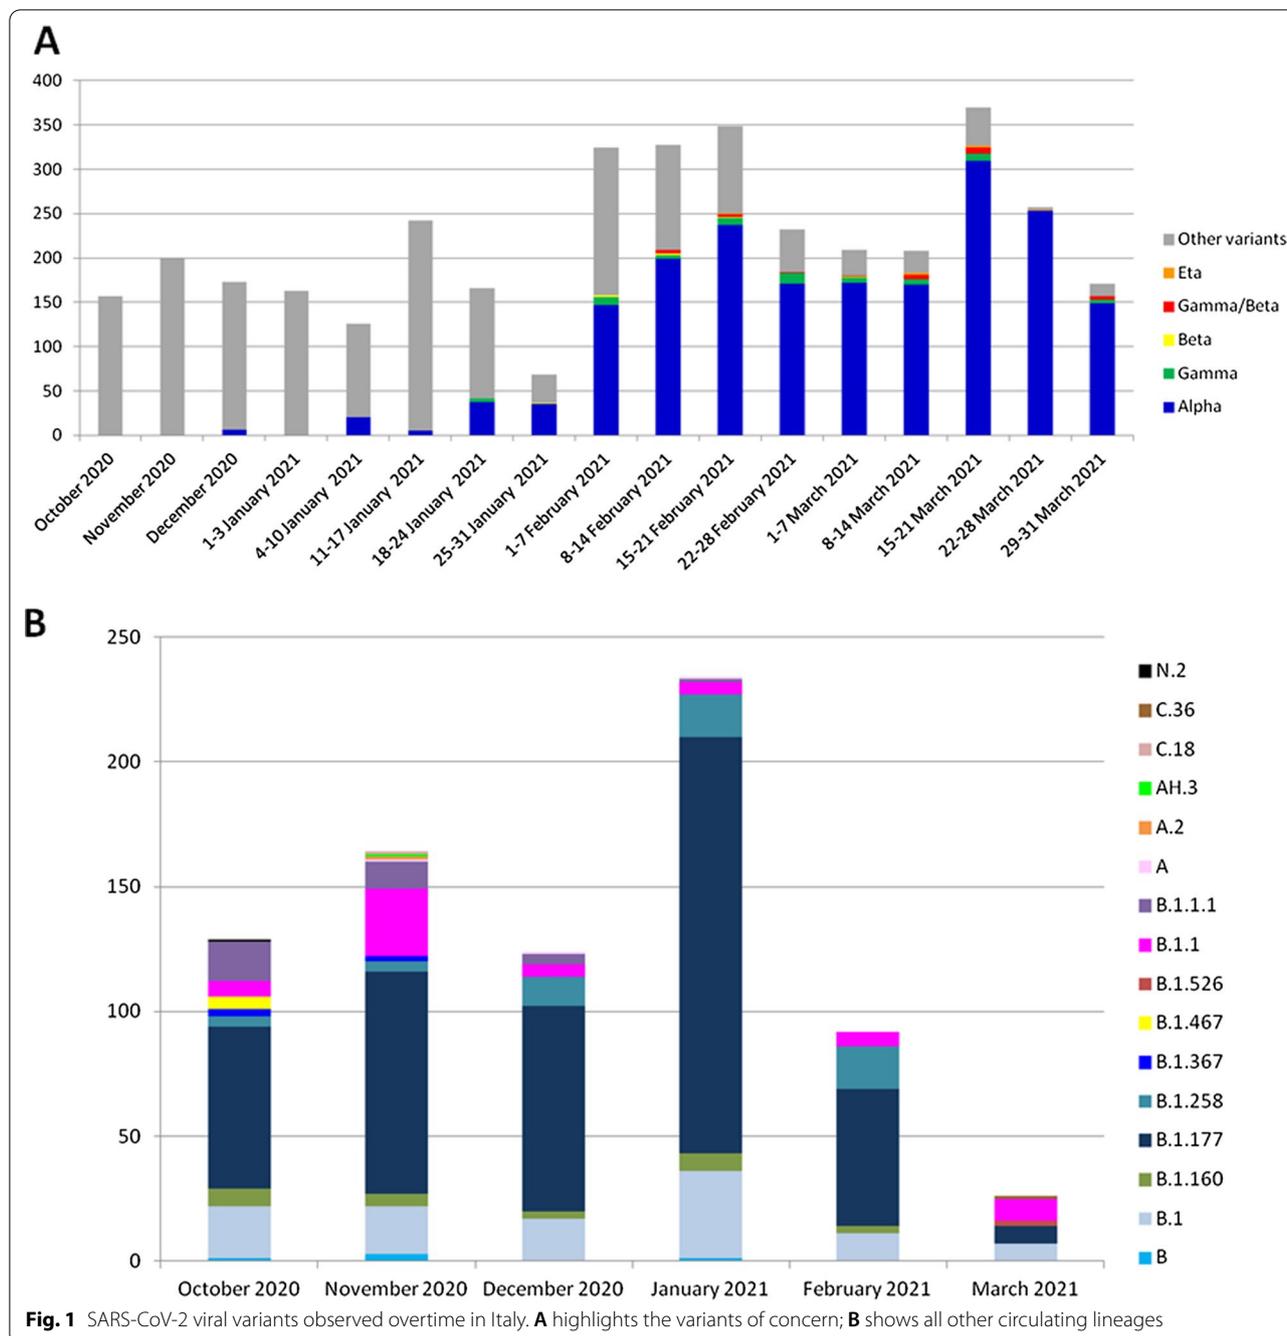

Spike sequences were obtained using home-made protocols. Full genome sequences were obtained with different protocols, by a modified version of ARTIC Protocol (<https://artic.network/ncov-2019>) using Illumina DNA Prep and IDT ILMN DNA/RNA Index kit (Illumina), by Ion AmpliSeq SARS-CoV-2 Research Panel (Thermo Fisher Scientific, Waltham, Massachusetts, USA) or by CleanPlex® SARS-CoV-2 Panel (Paragon Genomics Inc, Hayward, CA, USA). Sequencing was performed on Illumina Miseq or Nextseq platforms for all samples except for those from Marche that were sequenced with Ion GeneStudioTMS5 System instrument. The results were mapped and aligned to the reference genome obtained from GISAID (<https://www.gisaid.org/>, accession ID: EPI_ISL_406800) using Geneious Prime software v. 9.1.5 (Biomatters, Auckland, New Zealand) (<http://www.geneious.com>) or Torrent Suite v. 5.10.1 (Eufomatics Oy, Espoo, Finland) or BWA-mem and rescued using Samtools alignment/Map (Hinxton, UK) (v. 1.9).

SARS-CoV-2 sequences were classified using the Pangolin COVID-19 Lineage Assigner tool v. 3.1.5 (<https://pangolin.cog-uk.io/>) and Nextclade v. 1.4.0 ([https://](https://clades.nextstrain.org/)

clades.nextstrain.org/). Mutations were identified using Nextclade.

The table shows the analyzed data stratified according to different methodologies used for the variant monitoring and months of sampling collection.

The number of samples considered for variant monitoring increased from 4.2% (158/3744) in October to 32% (1215/3744) in March, due to the increasing interest in viral variants at global level. In the study period, the Alpha variant (B.1.1.7) significantly increased, growing from 3.5% (6/173) in December, to 86.7% (1054/1215) in March ($p < 0.001$). Particularly, from the second half of December this lineage was already present in Liguria (n=1 on the 18th), Campania (n=3, on the 28th) and Marche (n=2, on the 31st) (EPI_ISL_778869, EPI_ISL_778868), with only one known case related to return from UK. The most important increase in its prevalence was observed from the second week of January (20/126, 16.0%) to the end of the same month (35/68, 51.5%) reaching 73.7% (171/232) at the end of February. In parallel, the prevalence of previously circulating variants significantly decreased from 100% (158/158) to 9.4% (114/1215). The Gamma variant (P.1) was first detected in the second half of January in Campania (n=1), Lombardy (n=1) and Umbria (n=2), subsequently setting at around 2% in February (33/1234) and March (24/1215). Only few Beta and Eta variants (B.1.351 and B.1.525 respectively) cases were identified, never reaching 1% of the total samples analysed, being firstly detected in Liguria at the end of January and in Campania in mid-February, respectively. The B.1.258 lineage (also known as Scottish variant) was firstly observed in Campania, Marche and Piedmont in mid-October, 4 cases were reported in November in Campania (n=2) and Piedmont (n=2), thereafter it was only reported in Campania until February reaching a proportion of 18.5% (17/92) of total cases of other variants, including its descendant lineages (B.1.258.3, B.1.258.14). In half of March, two cases of the Iota variant (formally known as New York lineage B.1.526) were identified in Marche. Figure 1 shows

the main viral variants observed overtime. Concerning other variants, the main circulating lineage was B.1.177 that represented, together with its descendents (B.1.177.4, B.1.177.8, B.1.177.14, B.1.177.15, B.1.177.52, B.1.177.53, B.1.177.75), more than half of cases (50.4%, 54.3%, 66.1%, 71.4% and 59.8% from October to February). Despite limited data regarding lineage assignment in March (n = 28), we observed a 27% prevalence of B.1

and B.1.177 lineages (Fig. 1, Panel B). Clade assignment was available for a larger number of strains compared to lineage because these data was obtained also by spike sequencing highlighting the clear predominance of 20E(EU1) ranging from 43.2% (68/157) to 67.7% (189/279). Some noteworthy mutations were observed in different lineages: N439K in one lineage A and B.1, E484K in three B.1.177 and A222V + E484K + N501Y in clade 20E.

Conclusion

This study provides insights into the rapid change in the prevalence of SARS-CoV-2 variants over six months in Italy. Interestingly, we observed the first entry of Alpha variant in Lombardy in late December, in line with the identification of first retrospective data in UK on 20 September [9–11] and those reported by ISS-Istituto Superiore di Sanità (<https://www.iss.it/documents/20126/0/11-6-2021+SECONDO+BOLLETTINO+Varianti+SARS-CoV-2.pdf/7febfb3-c32b-7505-cc1e-2176fc12cdf6?t=1623430432808>). The introduction of Alpha variant, notoriously associated to higher transmissibility compared to other variants and to an increased rate of mortality reported in some studies, corresponds to the second relevant increase of infections registered in Italy during the second epidemic wave [12–14].

In addition to known variants of concern, we documented other minor variants that could be early warnings of upcoming changes. Continuous monitoring of all variants is mandatory to comprehensively investigate and keep track of virus evolution, particularly along with expanding vaccination still based on original strains that have been largely substituted by novel variants.
